Black carbon (BC) particles are emitted into the atmosphere by incomplete combustion processes, and removed by precipitation. The measurements of BC mass concentration in rainwater improve the quantitative understanding of BC loss because wet deposition is the major sink of BC. We measured BC mass concentration in the air ($M_{BC}$) and in rainwater ($C_{BC}$) simultaneously at Cape Hedo on Okinawa Island, Japan, in the East China Sea, from April 2010 to March 2013 in order to understand $C_{BC}$ in each rain event during 2010-2013 summer. The rainwater is collected by an automated wet-only sampler during a 24 period. Photo-absorption photometer with heated inlet (COSMOS) is used to measure $M_{BC}$. $C_{BC}$ was measured by a system consisting of an ultrasonic nebulizer and a Single Soot Photometer (SP2).

It is often heavy rain by cumulonimbus cloud during summer in East Asia, so that $M_{BC}$ an hour before raining is expected to be related to $C_{BC}$. However, the correlation between $M_{BC}$ and $C_{BC}$ in all rain events during 2010-2013 summer is not agreed ($r^2 = 0.12$). Then, we extracted the heavy rain events, which had positive convective available potential energy (CAPE). These extraction was performed with the National Centers for Environmental Prediction (NCEP) Final (FNL) Operational Global Analysis data every 6 hours. This result was that $C_{BC}$ was correlated with $M_{BC}$ ($r^2 = 0.47$).

In order to investigate if $C_{BC}$ (Estimated $C_{BC}$) is explained with $M_{BC}$ and the liquid water content, Estimated $C_{BC}$ is verified by comparing the observed $C_{BC}$. The liquid water content is maximum at the equilibrium level (EL) by the condensation process theoretically if the total water mixing ratio is conserved in the air parcel. If BC in the parcel is active as cloud condensation nuclei (CCN) at lifted condensation level and removed by precipitation at EL, the equation of Estimated $C_{BC}$ at EL is represented as $C_{BC} = M_{BC}/(m_v \times WCR)$. $m_v$ is the water vapor content an hour before raining at the ground level. Water condensation ratio (WCR) is the mass ratio of liquid water content to water vapor content, which is calculated with the NCEP reanalysis data. Compared with the observed $C_{BC}$, Estimated $C_{BC}$ is correlated with the observed $C_{BC}$ well ($r^2 = 0.68$). It suggests that Estimated $C_{BC}$ is correctly represented as $C_{BC}$ with $M_{BC}$ and the most liquid water content at EL. The observed $C_{BC}$ is three times higher than Estimated $C_{BC}$ because the cloud droplets including BC particles might be collected during falling down.
