Diachronic dynamics of human-environment interactions

Convener:*Takahiro Miyauchi(Department of Earth Sciences, Graduate School of Science, Chiba University), Toshihiko Sugai(Department of Natural Environmental Studies, Institute of Environmental Studies, Graduate School of Frontier Science, The University of Tokyo), Takashi AZUMA(Active Fault and Earthquake Research Center, National Institute of Advanced Industrial Science and Technology), Akira Ono(Meiji University Center for Obsidian and Lithic Studies), Chair:Osamu Fujiwara(Active Fault and Earthquake Research Center, National Institute of Advanced Industrial Science and Technology)
Thu. May 1, 2014 11:00 AM - 11:30 AM  414 (4F)
Humans have attained their specific development by indigenous cultures and evolved through environmental adaptation. The session raises issues of human-environment interactions, views from diverse changes of climate, ocean, land and biota having made striking influence on humans. It welcomes various fields from human-environment change and their chronometric dating among Quaternary disciplines.

11:15 AM - 11:30 AM
Paleolithic human activity and summer temperature recorded in oxygen isotope of Semisulcospira from Sakitari-do archeological site

3-min talk in an oral session
Hikaru FUJITA¹, Tomomi SONE¹, *Akihiro KANO¹, Tomoyo OKUMURA², Masaki FUJITA³, Shinji YAMASAKI³, Chiaki KATAGIRI³ (1.SCS Kyushu University, 2.JAMSTEC, 3.Okinawa Pref. Mus. &Art Mus.)
Keywords:Paleolithic age, oxygen isotope, Okinawa

Sakitari-do archeological site is located in Gyokusen-do cave system in Nanjyo City, Okinawa Prefecture. Since 2009, this site has yielded important remains including a 12.4-ka-old human canine (Yamasaki et al., 2012). One of the noticeable animal remains is Eriocheir crub. Large and uniform size of the forceps indicates individuals of autumn season when this crub grows into an adult. Paleolithic people may have stayed in this cave during autumn and eaten Eriocheir crub. In order to examine this hypothesis, this study focuses on Semisulcospira shell that was excavated together with Eriocheir. Semisulcospira is a freshwater gastropod that grows spiral shell. It is known that change in the water temperature was recorded in oxygen isotope of a series of samples collected along the spiral growth axis (Kano et al., 2008). If the Paleolithic people ate the gastropod, the oxygen isotopic value of the outermost sample indicates when it was taken. We analyzed the gastropod shell from two Paleolithic layers (19 ka and 12.4 ka) of the Sakitari-do site, as well as modern Semisulcospira collected a stream 5 km east from the site in late November 2013. Paleolithic specimens from the Sakitari-do often exhibit a sign-shaped oxygen isotopic curve. Amplitude of the change is ~2 permil that corresponds to ~8 degree temperature change under stable water isotopic composition. More importantly, the outermost value locates on an autumn position in many specimens, which support the hypothesis based on Eriocheir remains. In contrast, the modern Semisulcospira specimens that lack the sign-shaped pattern were young individuals that born in early summer. They recorded temperature change from summer to November. Comparing the summer oxygen values, the modern specimens are 1-1.5 permil lower than the Paleolithic specimens. If the oxygen isotopic value has been constant, it can be evaluated that the Paleolithic summer water was 4-6 degree
