Submarine groundwater discharge (SGD) often influences on biogeochemical properties in coastal seas. We observed spatial and temporal variations in SGD using ²²²Rn and seepage meter along the shoreline of Obama bay, Japan. The results showed SGD exists even in the shallow sea adjacent to the small water catchment area (~1 km²), where the range of the tide is relatively small (10 ~30 cm). The spatial and temporal variations in chlorophyll observed at the same time suggest that the SGD influences on primary production.

Keywords: land-ocean interaction, submarine groundwater discharge, coastal ecosystem, primary production
