[S-EM17]Geomagnetism, Paleomagnetism and Rock Magnetism

convener:Nobutatsu Mochizuki(Priority Organization for Innovation and Excellence, Kumamoto University),
Hisayoshi Shimizu(Earthquake Research Institute, University of Tokyo)

Mon. May 21, 2018 5:15 PM - 6:30 PM Poster Hall (International Exhibition Hall7, Makuhari Messe)

We are going to discuss the issues on the magnetic fields of the Earth and planets, paleomagnetism, rock-magnetism, and their applications. This session includes the following topics: (1) observation and analysis of the magnetic fields of the Earth and planets, (2) paleomagnetic field variations obtained from natural and archaeological materials, (3) numerical simulations on the magnetic fields of the Earth and planets, (4) measurements and theories of magnetic properties of rocks, minerals, meteorites and other materials, (5) climate changes and global and local surface tectonics based on the paleomagnetic measurements of rocks and sediments, (6) observations of the magnetic anomalies and the crustal magnetization models of the Earth, planets and satellites, and (7) developments of the experimental method and data analysis. The presentation and discussion will be made in Japanese or English in this session.

[SEM17-P10]Preliminary report on sedimentary structure and magnetostratigraphy of IODP Site U1490

Keywords:Magnetostratigraphy, IODP Expedition 363

The scientific objectives of International Ocean Discovery Program (IODP) Expedition 363 were to study regional and global climate variability across the Western Pacific Warm Pool (WPWP) from the middle Miocene to late Pleistocene. IODP Site U1490 (05°48.95′N, 142°39.27′E, 2341 meters water depth) is located on the northern edge of the Eauripik Rise and was cored to 270 m. The recovered pelagic sediments consist of calcareous and siliceous nannofossils with varying proportions of clay and ash. Seismic reflection data reveal a series of relict current-controlled mud waves that decrease in amplitude up-section shallower than a depth of 180 m. Formation of the present-day WPWP deep water masses in polar downwelling regions enriches them in dissolved oxygen. The presence of well oxygenated water masses at the location of Site U1490 helps to preserve ferrimagnetic minerals in the mudwaves. Shipboard analysis revealed that magnetic minerals between ~25 and 180 meters composite depth (mcd) had been altered by diagenesis and the paleomagnetic data were uninterpretable. However, in the upper ~25 mcd and below ~180 mcd, sediments display stable magnetization that spans from the present to early Pleistocene (0–1.9 Ma) and from the middle to late Miocene period (~9–19 Ma), respectively. The latter is an exceptionally long and continuous sediment sequence that provides an opportunity examine long-term variations of the paleomagnetic field. Here we develop a preliminary magnetostratigraphy for Site U1490 using the natural remanent magnetization (NRM) made on U-channel samples with stepwise alternate-field (AF) demagnetization in peak fields of 20–80mT. We improve the shipboard record by identifying two more reversals in the declination data after 20 mT AF demagnetization. Future work includes the measurement of anhysteretic remanent magnetization (ARM) and isothermal remanent magnetization (IRM) to estimate relative paleointensity and characterize rock magnetic variability.
