The gravestone seismology is the study that considered the mechanism of the earthquake by investigating the gravestone. We started the research because we thought we could understand the geology of the epicenter by using grave seismology. In particular, the points that we investigated are in the North of Osaka and Hokkaido Eastern Iburi. These points were damaged by very big earthquake. And we have some consideration through the fieldwork. The problem was how to treat relations of disaster situations of differences each regions and geology, and the geological features in our home town from the case past “Zenkoji Earthquake “. What we can learn from the past, how the present is, and what we should do in the future. These are our study that considered Grave seismology.
