On, April 1, 2018, we observed a star occultation of asteroid (51) Nemausa. From the collected data and the date from other observation points, we estimated the cross sectional view of Nemausa. We' ve also conducted a photometric observation to calculate Nemausa' s rotation period. From the two results, we estimated the possible shape of Nemausa. In addition, we compared the light curve of the actual data with the light curve of a model of the estimated shape.

Keywords: asteroid, photometric observation
