Delineation and characterisation of major tectonic provinces of
Dronning Maud Land (East Antarctica) and significance for Rodinia
assembly

We present a large new geochronological data set from a critical transition zone in central Dronning Maud
Land, East Antarctica, where Grenville-age rocks of the Maud Belt are juxtaposed along the juvenile
Tonian Oceanic Arc Super Terrane (TOAST). Previously, central Dronning Maud Land had been
interpreted as part of the Kuunga Orogen (580-500 Ma) by some researchers, because of the lack of
metamorphic ages of ca. 630-600 Ma, though based on a relatively small study. However, our new study
clearly highlights the significance of metamorphic ages also in the range from 670 –600 Ma in this region
and shows that a subdivision into Kuunga vs. East African Orogen is not valid. Our new data rather support
a long-lasting, protracted Late Neoproterozoic/Early Palaeozoic tectono-metamorphic history along the
margin of Kalahari. We can trace characteristic Kalahari-type rocks until the Wohlthat massive (12°E), to
the E of which typical TOAST-related rock crop out. The boundary zone coincides largely with the Forster
Magnetic Anomaly, a major aeromagnetic lineament in the region. The second part of this study includes
the age analyses of glacial drift from the southern side of the Dronning Maud Land Mts.. The moraines
stranded as a result of the northward flowing ice-sheet and they therefore should characterise the cryptic
subice geology inboard of the Dronning Maud Land Mts. Nine moraine bulk samples from 15-25°E
resulted in ca. 1100 new U-Pb zircon spot ages that range between ca. 2000 and 500 Ma. The very few
oldest Palaeoproterozoic ages come from the easternmost localities and may indicate a provenance of the
Ruker Craton. All samples are dominated by a major TOAST age peak of ca. 990 –900 Ma, clearly
indicating that the TOAST reaches far inland, as has also been suggested by geophysical data. In addition,
however, a significant Stenian age peak of ca. 1080 Ma also occurs. Although Late Mesoproterozoic ages
are common in both the Maud Province of western-central DML as well as in the Rayner Complex to the E,
the Stenian moraine sample differ with respect to composition and/or isotope geochemistry. They are
juvenile, with depleted mantle extraction ages around 1.3 Ga, are subduction-related, and therefore
resemble an early phase of oceanic arcs that was so far unknown in this region. Thus, TOAST related rocks
are produced over a protracted period of time from ca. 1080 to at least 900 Ma. There is no sign of major
metamorphic overprint immediately after crust formation. Therefore, these island arcs may have formed
independent or peripheral to Rodinia and may reveal major accretionary tectonics outboard of Rodinia.
Much later, the TOAST underwent major tectono-metamorphic overprint at 670 –500 Ma, as a result of
the extroversion of Rodinia and its subsequent incorporation into Gondwana.
