Temperature dependence of spin relaxation time
in (110)-oriented GaAs/AlGaAs quantum wells

To maintain spin polarization in non-magnetic materials is key issue to effectively utilize the spin information in operating spintronics devices such as spin-controlled laser [1]. A (110)-oriented GaAs/AlGaAs quantum wells (QWs) has attracted much attention since a very long electron spin relaxation time ($\tau_s > 1$ ns) was reported at room temperature (RT) [2]. We have recently succeeded in fabricating (110) GaAs/AlGaAs QWs, which can meet crucial demands (very flat surface, high emission efficiency and long $\tau_s$ value) for the practical spin laser, by optimizing growth conditions [3]. Such a high-quality sample would give us a good opportunity to clarify its effective spin relaxation mechanism by measuring the $\tau_s$ value as a function of temperature ($T$). Here, we report on a unique $T$ dependence of the $\tau_s$ for the (110) GaAs/AlGaAs QWs.

Several undoped samples with 20 periods of GaAs(10 nm)/Al0.3Ga0.7As(20 nm) QWs were fabricated on semi-insulating GaAs(110) substrate using molecular beam epitaxy (MBE) under the different V/III (As/Ga) flux ratios and growth temperature ($T_s$) [3]. The $\tau_s$ value was evaluated by polarization- and time-resolved photoluminescence (PL) measurements. Mode-locked Ti: Sapphire laser and the streak camera were respectively used as the pump laser and the PL detector. Excitation wavelength of the pump laser was fixed at 750 nm.

Figure 1 shows the dependence of the $\tau_s$ value on $T$ for the (110) QWs (V/III ratio of 60 and $T_s$ of 500 °C) which has the longest carrier lifetime at RT (4.4 ns) among our samples. It is clear that the $\tau_s$ takes a maximum around 150 K, indicating that there are at least two major spin relaxation mechanisms. It has been generally accepted that the increase with $T$ is due to the alleviation of Dyakonov-Perel dephasing mechanism. Dohrmann et. al. pointed out that the decrease in $\tau_s$ at high $T$ can be caused by the electron scatterings between different QW subbands [4]. The effect of the growth conditions on the $\tau_s$- $T$ plot would give us useful information to clarify the origin of the maximum in the $\tau_s$ - $T$ as well as the effective spin relaxation mechanism at high $T$.
