Introduction
We have developed a novel low temperature high rate sputtering technique. 1) In this technique c-axis highly aligned ZnO piezoelectric films were fabricated with a very high deposition rate (~15 μm/h). In this paper it is shown that these films deposited in this technique have less radiation damages to the substrates and deposited films than other sputtering techniques.

Description of New Equipment
In the conventional magnetron sputtering techniques, a magnet is fixed to the back of the target to produce a leakage flux on the target surface. In our system another solenoid coil is placed around a cylindrical bell jar to push away the leakage fluxes to the target surface. These two magnetic fluxes play an important role in this system. Moreover, as shown in Fig. 1, setting outer pole piece of the magnet behind the target to the outside of the target diameter, its utilization efficiency was greatly improved. Figure 2 shows how the magnetic field is compressed to the target surface. The parallel components to the target surface are effective to trap electrons and ionized particles.

Novel points of the system are:
1) The target utilization efficiency is higher than 80%. (Conventional magnetron: 30%)
2) The minimum target-substrate distance is 1 cm or less in order to be outside the plasma region because the plasma is compressed to the target surface and a disklike doughnut. (Conventional magnetron: 4 - 5 cm)

Experiments
C-V characteristics of Al-ZnO-Si02-Si(2)
(MZOS) structure were observed and shown in Fig. 3.
A 1000Å thermally oxidized Si02 was grown on the n-Si wafers (Nn = 2 x 1015/ cm3). An Al gate diameter was 0.5 mm. The surface-state charge density was estimated as Qss/q = 3.1 x 1011/cm2. ZnO films were deposited by our CMF-magnetron sputtering (A in Fig. 3) and conventional dc reactive sputtering (B in Fig. 3). As this figure shows no increase in fast-surface states were observed in Curve A though it was observed in Curve B. It is reported in the literature that a large hysteresis and large shift of VFB are observed in this MZOS structure. 3,4) But this stable C-V characteristics were independent of film deposition rate.

and scanning speed of C-V characteristics.

Next, ZnO films were etched off from MZO structure, and C-V characteristics of the etch-back MOS structure were observed and shown in Fig. 1(a) and (b). Dashed lines in the figure are C-V characteristics of original MOS structure at 1 MHz. Fig. 1(a) is for the etch-back MOS of Curve (a) in Fig. 3. These curves are same as those of original MOS structure, but they shift 0.6 V toward positive direction. It shows that negative charges are trapped in the SiO₂.

On the other hand, Fig. 1(b) is for the etch-back MOS of Curve (b) in Fig. 3. This figure shows that fast surface states are induced in SiO₂-Si interface and ionized charges are trapped in the SiO₂. From these experimental results we can conclude that the CMF-magnetron sputtering technique can deposit films with low radiation damages and high deposition rate.

Conclusion: Radiation damages of films deposited by the CMF-magnetron sputtering techniques were clarified. The sputtering conditions of ZnO are tabulated in Table 1. We believe that this technique will permit a great success to deposit SiO₂ and Si₃N₄ films for VLSI process. As the deposition temperature is low enough to deposit on plastics, we have deposited optical TiO₂ films on PMMA and it is possible to use He as a sputtering gas instead of Ar gas because of high deposition rate.
